Near-consistent robust estimations of moments for unimodal distributions

Tuban Lee

This manuscript was compiled on June 7, 2023

- Descriptive statistics for parametric models currently rely heavily
- 2 on the accuracy of distributional assumptions. Here, leveraging the
- 3 structures of parametric distributions and their central moment kernel
- distributions, a class of estimators, consistent simultanously for both
- a semiparametric distribution and a distinct parametric distribution, is
- proposed. These efficient estimators are robust to both gross errors
- 7 and departures from parametric assumptions, making them ideal
- for estimating the mean and central moments of common unimodal
 distributions. This article also illuminates the understanding of the
- common nature of probability distributions and the measures of them.

Most robust location estimators commonly used are symmetric owing to the prevalence of symmetric distributions. A γ -weighted Hodges-Lehmann mean (WHLM_{k,\epsilon}, γ) can achieve consistency for any γ -symmetric distribution. However, it falls considerably short of effectively handling a broad spectrum of other common distributions. Shifting from semiparametrics to parametrics, consider an estimator with a non-sample-dependent breakdown point (defined in Subsection ??) that is consistent simultanously for both a semiparametric class of distributions and a distinct parametric distribution, such a robust estimator is named with the prefix 'invariant' followed by the population parameter it is consistent with. Here, the recombined I-statistic is defined as

$$\operatorname{RI}_{d,\mathbf{k}_{1},\mathbf{k}_{2},k_{1},k_{2},\epsilon_{1},\epsilon_{2},\gamma_{1},\gamma_{2},n,LU_{1},LU_{2}} := \lim_{c \to \infty} \left(\frac{\left(LU_{1\mathbf{k}_{1},k_{1},\epsilon_{1},\gamma_{1},n}+c\right)^{d+1}}{\left(LU_{2\mathbf{k}_{2},k_{2},\epsilon_{2},\gamma_{2},n}+c\right)^{d}} - c \right),$$
